SYSTEMS AND METHODS FOR MOUNTING A FUEL SYSTEM

CROSS-REFERENCE

This application claims priority to U.S. Provisional Patent Application Ser. No. 61/716,470, filed on Oct. 19, 2012, which is entirely incorporated herein by reference.

BACKGROUND OF THE INVENTION

Vehicles, such as natural-gas powered vehicles, typically require the use of fuel tanks under certain pressure or temperature requirements. The fuel tanks can be mounted on the vehicle. Side-mounted compressed gas tanks are rigidly mounted to a vehicle chassis in a complicated and lengthy procedure that requires the removal of the vehicle from the assembly line. Such techniques for mounting a fuel systems onto vehicles are often very time consuming and costly.

SUMMARY OF INVENTION

Recognized herein is the need for devices, systems and methods to improve performance, decrease installation time and improve safety of mounting fuel supply to a vehicle.

The invention provides devices, systems and methods for mounting a fuel system to a vehicle. Some embodiments provide systems and methods for mounting a fuel system comprising a fuel tank to a vehicle chassis using a bracket, which may be a multi-part bracket, and may be referred to as a "drop and go" bracket.

An aspect of the invention is directed to a drop and go bracket comprising: a first bracket portion configured to be attached to a vehicle chassis; and a second bracket portion configured to be attached to a vehicle fuel system, wherein the first bracket portion and the second bracket portion are configured to be engaged and connected to one another in a manner that (i) mounts the vehicle fuel system to the vehicle chassis and (ii) prevents substantial translation without rotation between the first bracket portion and the second bracket portion in a lateral direction and in a vertical direction without the aid of additional fasteners.

Another aspect of the invention is directed to a vehicle fuel mounting system comprising: a first bracket portion attached to a vehicle chassis; and a second bracket portion attached to a vehicle fuel system, wherein the first bracket portion and the second bracket portion are configured to be engaged and interlock in order to mount the vehicle fuel system to the vehicle chassis without the aid of additional fasteners.

Furthermore, aspects of the invention are directed to a method for mounting a fuel system to a vehicle comprising: attaching a first bracket portion to a vehicle chassis; attaching a second bracket portion to a vehicle fuel system; and attaching the second bracket portion attached to the vehicle fuel system to the first bracket portion attached to the vehicle by one or more of the following: (i) sliding a part of the first bracket portion into a cutout, indentation, or hole of the second bracket portion, or (ii) sliding a part of the second bracket portion into a cutout, indentation, or hole of the first bracket portion.

Other goals and advantages of the invention will be further appreciated and understood when considered in conjunction with the following description and accompanying drawings. While the following description may contain specific details describing particular embodiments of the invention, this should not be construed as limitations to the scope of the invention but rather as an exemplification of preferable

2

embodiments. For each aspect of the invention, many variations are possible as suggested herein that are known to those of ordinary skill in the art. A variety of changes and modifications can be made within the scope of the invention without departing from the spirit thereof.

INCORPORATION BY REFERENCE

All publications, patents, and patent applications mentioned in this specification are herein incorporated by reference to the same extent as if each individual publication, patent, or patent application was specifically and individually indicated to be incorporated by reference.

BRIEF DESCRIPTION OF DRAWINGS

The novel features of the invention are set forth with particularity in the appended claims. A better understanding of the features and advantages of the present invention will be obtained by reference to the following detailed description that sets forth illustrative embodiments, in which the principles of the invention are utilized, and the accompanying drawings of which:

FIG. 1 is a schematic of a fuel system carried on board a vehicle.

FIG. 2 is a photograph of a drop and go bracket.

FIG. 3 is a perspective view of a chassis bracket of a drop and go bracket.

FIGS. 4A-G schematically show a sequence of steps during engagement of a chassis bracket with a system bracket.

FIG. 5 is a photograph of mounting of a fuel system using a drop and go bracket and a lift assist device.

FIGS. 6A-D show multiple views of an example of a fuel system bracket.

FIGS. 7A-D show multiple views of an example of a chassis bracket.

FIGS. 8A-H show multiple views of a combined fuel system bracket and chassis bracket.

DETAILED DESCRIPTION OF INVENTION

The invention provides systems and methods for mounting a fuel system to a vehicle. In some embodiments, the invention provides systems and methods for mounting a fuel system comprising a fuel tank to a vehicle chassis using a bracket, which may be a multi-part bracket, and may be referred to as a "drop and go" bracket. Various aspects of the invention described herein may be applied to any of the particular applications set forth below or in any other type of mounting and/or attachment setting. The invention may be applied as a standalone method or system, or as part of an integrated mounting and/or attachment system. It shall be understood that different aspects of the invention can be appreciated individually, collectively, or in combination with each other.

FIG. 1 is a schematic of a vehicle 100 with a fuel system 110 mounted thereon. A vehicle 100 may be any type of vehicle known in the art. A vehicle may be a truck, such as a light duty truck (e.g., class 1, class 2 or class 3), medium duty truck (e.g., class 4, class 5 or class 6), or heavy-duty truck (e.g., class 7 or class 8). In some embodiments, the vehicles may be cars, wagons, vans, buses, high-occupancy vehicles, dump trucks, tractor trailer trucks, transit, refuse or heavy-duty vehicles, or any other vehicles. The vehicle may have any weight. For example, the vehicle may weigh more than or

equal to about 5000 lbs, 7,500 lbs, 10,000 lbs, 12,500 lbs, 15,000 lbs, 17,500 lbs, 20,000 lbs, 22,500 lbs, 25,000 lbs, 30,000 lbs, or 35,000 lbs.

The fuel system **110** may be mounted to the vehicle in various configurations. For example, in a side-mount configuration, a fuel system **110** may be installed on the side of the vehicle frame rail (not shown). Fuel systems may be installed on one or both sides of the vehicle, providing, for example, standard fuel capacities, measured in diesel gallon equivalents (DGE), of 40 DGE, 60 DGE, 80 DGE, 100 DGE, or 120 DGE or more. In another example, in a behind-the-cab configuration, a fuel system **110** may be installed behind the cab on the vehicle frame rail, providing, for example, standard fuel capacities of 45 DGE, 60 DGE, 75 DGE or 100 DGE. In a further example, in a roof mount configuration, a fuel system **110** may be installed on the roof of the vehicle body or in a custom integration, providing a wide range of customizable fuel capacities. In an additional example, in a front-of-the-body configuration, a fuel system **110** may be installed in front of the vehicle body, providing, for example, standard fuel capacities of 60-100 DGE. In some embodiments, mounting to the vehicle chassis may include, but is not limited to, the vehicle frame rail.

A vehicle **100** may be propelled by a fuel, including, but not limited to, compressed natural gas (CNG), liquefied natural gas (LNG), liquefied petroleum gas (LPG), Diesel fuel, gasoline, dimethyl ether (DME), methanol, ethanol, butanol, Fischer-Tropsch (FT) fuels, hydrogen or hydrogen-based gas, hythane, HCNG, syngas and/or other alternative fuels or fuel blends. For example, natural gas in the form of CNG or LNG may be an alternative fuel of choice for transit, refuse, and many other heavy-duty vehicles.

The fuel may be stored as a compressed gas, as a liquefied gas or as a liquid under its own vapor pressure. The fuel may be stored in an on-board fuel system **110**, comprising a fuel tank, vessel, or any other type of device capable of containing a fuel in compressed gas, liquefied gas or liquid form. Any description of a fuel tank herein may also be applied to other types of fuel containing devices.

The fuel tank may be configured in accordance with the chosen fuel storage mode. For example, compressed gases, such as CNG, may require that the fuel tank be outfitted with adequate high pressure components (e.g., high pressure seals, relief valves, compression devices), wherein high-strength and lightweight materials may allow CNG pressures up to, for example, 3,600 psig. In another example, liquefied gases, such as LNG, may require that the fuel tank be outfitted with adequate liquefaction components (e.g., coolers, liquid-vapor separators, insulation). LNG systems may operate at pressures of, for example, 0 psig, 50 psig, 100 psig, 150 psig, 200 psig, 250 psig, 300 psig, or 350 psig and temperatures of, for example, -259° F., -223° F., -200° F., -186° F., -175° F., -167° F., -158° F., or -150° F., requiring the use of cryogenic (about -260° F.) piping systems and vacuum-insulated storage tanks.

In some embodiments, a vehicle **100** may contain a single fuel tank. In other embodiments, the vehicle may contain a plurality of fuel tanks. The tanks may or may not have the same characteristics. The tanks may be mounted to any portion of the vehicle. In some embodiments, the tanks may be mounted to a side of the vehicle. One, two, or more tanks may be mounted on a single side of the vehicle, or on each side of the vehicle. The side-mounted tanks may at least partially protrude from a side surface of the vehicle.

The one or more fuel tanks may provide storage for a predetermined amount, or capacity, of fuel. For example, for natural gas measured in diesel/gasoline gallon equivalents

(where 1 gasoline gallon equivalent (GGE)=standard cubic feet (SCF) of natural gas divided by 123, and 1 diesel gallon equivalent (DGE)=standard cubic feet (SCF) of natural gas divided by 139), the amount of fuel provided on board the vehicle may be, for example, up to about 28 DGE, 45 DGE, 52 DGE, 60 DGE, 63 DGE, 70 DGE, 75 DGE, 80 DGE, 88 DGE, 92 DGE, 140 DGE, 100 DGE, 105 DGE, 120 DGE, 140 DGE, 160 DGE, 176 DGE, or more than 176 DGE.

The fuel tank may have any size and/or weight. For example, the fuel tank may be larger than, smaller than, or about the same size as a 5 gallon tank, 7 gallon tank, 10 gallon tank, 15 gallon tank, 20 gallon tank, 25 gallon tank, 30 gallon tank, 40 gallon tank, 50 gallon tank, 70 gallon tank, 90 gallon tank, 110 gallon tank, 130 gallon tank, 150 gallon tanks, or 170 gallon tank. The fuel tank may weigh more than, less than, or equal to about 0.01 tons, 0.03 tons, 0.05 tons, 0.07 tons, 0.1 tons, 0.2 tons, 0.3 tons, 0.5 tons, 0.7 tons, or 1.0 tons. For example, the fuel tanks may be of cylindrical form with dimensions (radius in inches×length in inches) of, for example, 25"×39", 25"×61", 25"×80", 25"×90", 26"×80", 26"×90", 26"×120", 26"×76", 16"×80", 21"×86", 16"×120", 21"×70", 21"×86", and one or more cylinders may be combined to achieve a predetermined total fuel capacity.

The fuel system **110** may be capable of containing a fuel at a predetermined pressure. For example, the fuel system **110** may be capable of containing a fuel having a pressure of less than or equal to about 10000 psig, 8000 psig, 7000 psig, 6500 psig, 6000 psig, 5500 psig, 5000 psig, 4750 psig, 4500 psig, 4250 psig, 4000 psig, 3750 psig, 3500 psig, 3250 psig, 3000 psig, 2750 psig, 2500 psig, 2000 psig, 1500 psig, 1000 psig, 500 psig, 300 psig, 100 psig, or less. Optionally, the fuel system may be structurally capable of containing a fuel having a high pressure value, such as at least the pressure values described above.

In embodiments requiring cooling and/or insulation, such as in LNG fuel systems, the fuel system components may be appropriately outfitted with insulation, chillers and/or other components known in the art. For example, the fuel transfer lines and the fuel tank may be wound with insulation.

The fuel system **110** may have one or more fuel outputs. The fuel output may transfer the fuel to another part of the vehicle **100**, such as an engine. In one example, the fuel may be output to mix with air in the cylinder of an engine. The fuel may be used in the process of propelling the vehicle. Further, the fuel system **110** may have one or more fuel inputs. The fuel inputs may transfer the fuel from an external fuel supply to another part of the vehicle **100**, such as the one or more on-board fuel tanks.

The fuel system **110** may comprise one or more fuel tanks, fuel tank fill systems, fuel distribution systems, electronic sensors and control units, and/or other components or subsystems, such as the devices, systems and methods provided in U.S. Provisional Patent Application Ser. No. 61/613,933 ("SMART COVERS"), filed Mar. 21, 2012, which is incorporated herein by reference in its entirety. The fuel system **110** may be housed in a cover, which may be mounted to the vehicle, and may serve to contain and protect the fuel tank and other fuel system components. The cover may be made of a variety of materials, including, but not limited to, metal or metal alloys (e.g., steel, iron, aluminum, titanium, copper, brass, nickel, silver, or any alloys or combinations thereof), composite materials (e.g., carbon fiber, fiberglass), or polymer materials. The cover may be made of a single material or may comprise multiple pieces made of different materials. The fuel system **110** may be partially housed in the cover. In some embodiments, one or more components of the fuel system **110** may reside outside of the cover. For example, the

5

fuel distribution system components may reside partially inside and partially outside of the cover, or fully outside (e.g., within the body of the vehicle) of the cover.

One or more fuel systems **110** may be provided on board the vehicle and may be housed in a unified cover, in separate covers, or a combination thereof. For example, multiple fuel tanks may be housed in one cover. Some fuel tanks may be provided in a common cover, while other fuel tanks may be provided in separate covers. The fuel system **110** may be rated at a predetermined pressure (e.g., 3600 psig). The cover may or may not be configured to withstand explosion within the fuel system **110**.

In accordance with an aspect of the invention, the fuel system **110** may be mounted to the vehicle chassis, such as, for example, to the vehicle frame rail, using one or more drop and go brackets. The bracket(s) may be fabricated from any material. In some instances, the bracket(s) may include a metal or metal alloy including but not limited to steel, iron, aluminum, titanium, copper, brass, nickel, silver, or any alloys or combinations thereof. In some instances, the bracket(s) may include a composite material, such as carbon fiber, or fiberglass. The bracket(s) may include a polymer. Separate portions of each bracket, such as a first bracket part and a second bracket part, may be formed from the same material or from different materials. In some cases, the bracket(s) or parts thereof may be formed of a shock-absorbing material. The bracket may be a multi-part bracket having two or more parts that may be joined together. The parts of the bracket may be separably joined, or may be permanently affixed to one another.

FIG. 2 shows an embodiment of a drop and go bracket **220** with two separable bracket parts **221** and **222**. The bracket **220** may be mounted to a vehicle frame **201** on a vehicle chassis (e.g., on the side of a truck) in a configuration where the fuel system bracket **221** is attached to a fuel system (not shown) and the chassis bracket **222** is attached to the frame rail **201**. The chassis bracket **222** may include pins or interlocking (mating) features **224** that allow the bracket **220** to be installed on the chassis **201**. A mating bracket, such as the fuel system bracket **221**, may be installed onto the fuel system (e.g., onto a CNG or LNG tank), and may allow the brackets **221**, **222** to easily and quickly assemble to, each other during mounting. During mounting, the bracket **221** on the fuel system or fuel tank may be connected to the chassis bracket **222** on the chassis **201** by bringing the fuel system bracket **221** together with the chassis bracket **222** such that their mating features engage. The bracket parts may be engaged in a timely manner without requiring any additional adjustment, alignment, dislocation and/or relocation of the chassis **201**, thus enabling bracket assembly and fuel system mounting directly on a vehicle production line. The bracket **220** allows the fuel system to easily drop in place in a go-ready configuration.

The bracket **220** may comprise various fasteners, connectors (e.g., nuts and bolts, screws), locks, snap fits, pins, interlocking (mating) features and/or other connecting and/or guiding members. These members may be used to mate and/or connect the bracket **222** to the chassis (e.g., via one or more members **224**) and/or the bracket **221** to the fuel system. After the engagement of the brackets **221** and **222**, the members may be used to mate and/or connect the bracket **222** with the bracket **221** (e.g., via one or more members **226**), the bracket **221** to the chassis and/or the bracket **222** to the fuel system. Further, one or more members **225** may be provided to connect a structural member (not shown) to the region **223** of the assembled bracket **220**. The structural member may be, for example, a single plate, or one or more additional brackets.

6

The structural member may be attached using any of the connecting and/or guiding members herein. Springs, tension cords, elastics and/or other variable compression parts may be used to provide connecting means on the bracket **220**. In some cases, the members may be removably connected, such as, for example, when using nuts and bolts. Alternatively, the members may be permanently connected, such as, for example, when sealed by glue, heat seal or melting, soldering, brazing, deformation of mating features and/or other means. The connecting and/or guiding members may be provided directly on the brackets **221**, **222** (e.g., mating features). Separate connecting and/or guiding members may be provided to interface with connecting and/or guiding members on the brackets (e.g., a nut and bolt interfacing with apertures on the brackets).

In alternative embodiments of the invention, additional numbers of bracket parts may be provided. For example, three, four, five, six or more bracket parts may be provided. The bracket parts may engage and/or be connected with each other using one or more of the connecting and/or guiding members described herein. The bracket parts may or may not be engaged/connected prior to mounting of the fuel system to the vehicle chassis. For example, at least two bracket parts may be engaged/connected while a third and a fourth bracket part may be engaged with one or both of the preceding parts during mounting. In another example, all bracket parts may be engaged/connected during mounting. In yet another example, all but two parts (which may be composite parts) may be engaged/connected prior to mounting, and so forth in a variety of other combinations.

Some embodiments of the invention may provide one or more means for mounting the fuel system to the vehicle in addition to the drop and go bracket. For example, the drop and go bracket may be used to mount the fuel system to the vehicle on the production line. At a later time, the fuel system and the vehicle may be connected using additional connectors and/or other brackets.

The connecting and/or guiding members may be formed from the same material as the rest of the bracket or from different materials. For example, one or more fasteners may be formed from a stronger steel material than one or more of the bracket parts, which may be formed of a different steel material or of a more lightweight material such as aluminum or composite. One or more connecting and/or guiding members may be formed of shock-absorbing material. In some instances, break-away pins or other members may be formed of a more breakable material than the rest of the bracket. The break-away pins may be formed of a more brittle material, weaker material, fatigued material, or may have any other characteristic relative to the other bracket parts. The connectors may be designed to break upon impact. Systems and methods provided herein may be combined with or modified by other systems and methods, such as systems and methods provided in U.S. Provisional Patent Application Ser. No. 61/612,878 ("BREAK-AWAY BRACKET"), filed Mar. 19, 2012, which is incorporated herein by reference in its entirety.

FIG. 3 is a perspective view of a chassis bracket **322** of a drop and go bracket. The chassis bracket **322** may be integrally formed, formed of one or more parts connected together in a permanent or removable fashion and/or a combination thereof. The chassis bracket may comprise various connecting and/or guiding members, such as, for example, members **324**, **325**, **327** and **328**. In one embodiment, the members **324** may be used to secure the chassis bracket to a chassis using one or more nuts and bolts or other connecting and/or guiding members described herein. The members **325** may be used to connect a plate (not shown) to the chassis

bracket 322 and a mating system bracket after the two have been engaged. Embodiments of the invention may only require the plate or portion to be connected in a single location positioned in a top portion of the engaged brackets (e.g., region 223 in FIG. 2). For example, only a top bolted portion may be provided. Some embodiments of the invention may or may not provide bolted or otherwise connected portion in multiple locations.

Members 327, 328 may be provided to guide and/or interlock with mating members provided on the fuel system bracket. The groove 328 may vary in length or profile to achieve a desired path of the mating components. For example, the circular member 327 may slidably engage and a semicircular or ellipsoidal feature on the system bracket. The two mating features may slide into a position where they interlock. In another example, the groove member 328 may guide and engage with a mating member, such as a pin, provided on the system bracket. The pin may move in the groove 328 to an end position. In some cases, features may be provided on the members 327, 328 and/or mating members on the system bracket to allow for the mating parts to click or interlock in place in the end position. The interlock may be permanent or reversible. For example, the mating parts may interlock such that dislocation is not possible without application of a predetermined amount of force. Embodiments of the invention may also provide mating features to complement each other to lock the brackets in place with respect to each other. For example, engagement of the circular pin member 327 with a mating member (e.g., circular cutout shape) on the system bracket may restrict the relative movement of the brackets such that when a mating member (e.g., a pin) on the system bracket engages with groove member 328, the brackets may not be movable with respect to each other than in one or more predetermined directions. Such mutual restraint may be particularly beneficial in the end (fully engaged) positions of the guiding members.

The chassis bracket 322 may further comprise one or more structural members 329. Such members may be integrally formed with one or more parts of the chassis bracket, may be connected to the chassis bracket or a combination thereof. The structural member 329 may have a functionality that lightweight the chassis bracket. For example, as shown in FIG. 3, the structural members 329 may be a series of plates or steps. In another example, a honeycomb structure may be provided such that a lightweight but strong (e.g., impact resistant) structure is obtained. The member 329 may also be used as a connecting and/or guiding member. For example, it may lock in with complementary features provided on the system bracket.

FIGS. 4A-G schematically show a sequence of steps during engagement of a chassis bracket 422 with a fuel system bracket 421. A close-tolerance fit of the brackets 421, 422 may be maintained by installation tooling. The fuel system bracket 421 may be mounted to a fuel system or fuel tank, for example via surface 430, and may be moved in a direction toward the chassis bracket 422 as shown. The chassis bracket 422 may be mounted to a vehicle chassis, for example via surface 431, and may be kept stationary during mounting. The bracket 421 may be moved in the indicated direction such that a member 432 (e.g., a pin) on bracket 421 engages with bracket 422 along a surface 433. The bracket 421 may continue to move along surface 433 to a position where member 432 encounters a groove member 428 (FIG. 4D). Meanwhile, cutout member 434 on the bracket 421 may be brought in proximity of pin member 427 on the bracket 422 as a result of the movement of the bracket 421 toward the bracket 422.

Next, the member 432 may move or slide in the groove member 428 such that the two brackets are brought further together along multiple directions, as illustrated by the arrows in FIGS. 4E-F, bringing members 434 and 427 in closer proximity and alignment. As shown in FIG. 4F, when the member 432 approaches its end position within the groove 428, the members 434 and 427 may engage. Further alignment and final positioning of the brackets may result in the configuration shown in FIG. 4G, wherein the member 432 has reached its final position with respect to groove 428, and the cutout 434 has been situated on the pin 427. As described elsewhere herein, engagement of the brackets 421, 422 may not be limited to the members/surfaces 432, 433, 428 and 434, 427.

In some instances, a multi-point connection may be provided. For example, when the brackets 421, 422 are brought together, an upper point of connection 432 and a lower point of connection 427 can be provided. Such multiple points of connection can provide additional stability to the connection of the fuel system to the vehicle chassis. Any number or placements of points of connection may be provided. In some instances, the connections may be provided via pin and cutout member as illustrated. Alternatively, any interlocking mechanism may be used to provide connections.

Optionally, when the two parts are fully engaged, the weight of the fuel system may pull down the fuel system bracket 421. The brackets may be held together via gravity. The interlocking features of the brackets may prevent the brackets from substantially moving relative to one another in a lateral or up-and-down direction. In some instances, when the parts are engaged, the movement between the brackets will be restricted along one, two or three axes of motion. For example, the brackets do not substantially move relative to one another in a purely lateral direction (e.g., fuel system toward or away from vehicle, or side shifting between the fuel tank and the vehicle). Optionally, the brackets do not substantially move relative to one another in a purely vertical direction (e.g., up and down relative to a surface upon which the vehicle rests). In some instances, a combination of motions in both a lateral and vertical direction, rotation of one bracket relative to another, or twisting may be required to separate the brackets once engaged. Once the parts are engaged, an additional attachment mechanism may be used to keep the brackets in place and prevent them from slipping apart.

Once the two parts engage, a top plate (not shown) may be bolted or otherwise fastened on a surface 423 so that the brackets 421 and 422 do not bounce up and out as indicated in FIG. 4G. Further, the various connecting members (e.g., nuts and bolts holding the body of the brackets 421 and 422 together and not identical to the top plate) may be used to secure the brackets together. One or more other connecting members may be used prior to connecting the top plate, concurrently with connecting the top plate and/or after connecting the top plate. In some embodiments, only the top plate may be used to secure the brackets, without requiring plates or connectors to be provided from any other side or direction of the drop and go bracket.

The multi-part drop and go bracket configuration may permit a fuel system to be mounted onto a vehicle using very few distinct parts. For example, the brackets may already be mounted onto a fuel system and chassis respectively. The brackets may engage with one another. A top plate or other attachment mechanism may be used to secure the brackets. In some instances, only, 2, 3, 4, 5, 6, 7, 8, 9, or 10 separate pieces may be used during the mounting of the fuel system to the vehicle.

FIGS. 6A-D are illustrations of an alternative bracket design. A fuel system bracket **600** configured to attach to a vehicle fuel system is shown. The fuel system bracket may have a curved surface **602** configured to engage or accommodate a curved surface of a fuel tank. The fuel system bracket may also have a shaped surface **610** configured to come into contact with a chassis bracket. The shaped surface may be provided to be complementary to a profile of the chassis bracket. Thus, when the fuel system bracket is engaged with the chassis bracket, the side **612** of the bracket may lie flush against the surface to which the chassis bracket is attached.

The fuel system bracket **600** may have one or more interlocking feature configured to mate with one or more corresponding feature of the chassis bracket. For example, one or more holes **620** or indentations may be provided. The fuel system bracket may have a top lip **622**. The underside of the top lip may be smooth or may include an overhanging feature that may be configured to hook over one or more feature from the chassis bracket. For example, a protrusion may be provided to be inserted into an indentation or hole of the chassis bracket. The underside of the top lip or surface of the fuel system bracket may have an indentation or hole configured to accept a protrusion or other feature from the chassis bracket. The brackets may be configured to hook together.

A fuel system bracket may have an interior surface **645** capable of contacting and/or mating with a portion of the chassis bracket. When weighted with a vehicle fuel system, the fuel system bracket interior surface may rest against a surface of the chassis bracket and provide additional support or stability. For example, a hole may be provided in the interior surface that may align with a hole or protrusion of the portion of the chassis bracket. The interior surface may be slanted at a non-orthogonal angle relative to the vehicle chassis surface when mounted.

The fuel system bracket may include one or more holes **630** or other features that may permit the fuel system bracket to be attached to a vehicle fuel system. For example, one or more fastener or other fastening techniques described elsewhere herein may be used to attach the fuel system bracket to the vehicle fuel system. The fuel system bracket may be attached to the vehicle fuel system prior to being engaged with a chassis bracket.

FIG. 6A shows a front perspective view of the fuel system bracket **600**. A side configured to interface with the fuel system **602** may be curved or configured to complement the shape of the fuel system cover or a fuel tank.

FIG. 6B shows a rear perspective view of the fuel system bracket **600**. A side configured to interface with a chassis bracket **610** may be shaped to complement or accommodate the shape of the vehicle chassis bracket. The side configured to interface with the chassis bracket may be opposite the side configured to interface with the fuel system. An interior surface **645** may be integrally formed as part of the bracket. The interior resting surface may be provided as a ridge, solid piece, tab, or have any other configuration.

FIG. 6C shows a top view of the fuel system bracket **600**. The fuel system bracket may have one or more features, such as holes **620a**, **620b**, **620c**, **620d**, **620e**, indentations, or protrusions. The features **620a**, **620b** may mate or interlock with corresponding features in a chassis bracket. The features may provide through holes **620c**, **620d**, **620e** in conjunction with the chassis bracket for through holes. The features may have different shapes and/or dimensions from one another or may have matching shapes and/or dimensions. For example, the interlocking features may be substantially circular, elliptical, semi-circular, crescent shaped, rectangular, trapezoidal or have any other shape.

FIG. 6D shows a rear view of the fuel system bracket **600**.

FIGS. 7A-D are illustrations of an alternative bracket design. A chassis bracket **700** configured to attach to a vehicle chassis is shown. The chassis bracket may have a flat surface **702** configured to rest against a surface of a vehicle chassis. The chassis bracket may also have a shaped outer surface **710** configured to come into contact with a fuel system bracket. The shaped surface **710** may engage with a complementary shaped profile **610** of the fuel system bracket. Thus, when the fuel system bracket is engaged with the chassis bracket, a substantially flat surface may be formed by the chassis bracket surface **702** and the fuel system bracket **612**.

The chassis bracket **700** may have one or more interlocking feature configured to mate with one or more corresponding feature of the fuel system bracket. For example, one or more protrusions **720** may be provided. The chassis bracket may have a top surface **722**. The topside of the top surface may be smooth or may include other features such as protrusions, indentations or holes **724** that may be configured to mate with complementary portions of the fuel system bracket. For example, a protrusion **720** may be provided to be inserted into an indentation or hole **620** of the fuel system bracket.

The chassis bracket may include one or more holes **730** or other features that may permit the chassis bracket to be attached to a vehicle chassis. For example, one or more fastener or other fastening techniques described elsewhere herein may be used to attach the chassis bracket to the vehicle chassis. The chassis bracket may be attached to the vehicle chassis prior to being engaged with a fuel system bracket.

FIG. 7A shows a front perspective view of the chassis bracket **700**. A side configured to interface with the fuel system bracket **712** may be curved or configured to complement the shape of the fuel system bracket. The chassis bracket may include a lower portion **715** that may be configured to contact or mate with an interior surface **645** of the fuel system bracket. The lower portion of the chassis bracket may be slanted to be non-orthogonal relative to the surface **702** configured to contact the chassis.

FIG. 7B shows a side view of the chassis bracket **700**. The chassis bracket may have one or more shaped features such as protrusions **720**, holes, or indentations configured to mate with or interlock with a feature of the fuel system bracket. Optionally, the lower portion **715** of the chassis bracket may include one or more features, such as protrusions, holes, or indentations. This may permit the lower portion of the chassis to mate with or interlock with an interior surface **645** of the fuel system bracket, and/or may provide an aligned through-hole with a through-hole of the fuel system bracket.

FIG. 7C shows a rear view of the chassis bracket **700**. A rear surface **702** of the chassis bracket may be configured to contact a vehicle chassis, frame, or other surface. The chassis bracket may include one or more through-holes **730** or other features that may permit the chassis bracket to be connected to the chassis.

FIG. 7D shows a top view of the chassis bracket **700**. The top surface **722** of the chassis bracket may be configured to contact an upper interior surface of the fuel system bracket. One or more protrusions (upper hook) **720** of the chassis bracket may pass through a through-hole **620a**, **620b** of the fuel system bracket. One or more holes **724** of the chassis bracket may be aligned with through-holes **620c**, **620d**, **620e** of the fuel system bracket. A fastener or other component may pass through the aligned through-holes.

FIGS. 8A-H show an example of a fuel system bracket **800** engaged with a chassis bracket **850**. The fuel system bracket

11

may be configured to attach to a vehicle fuel system and the chassis bracket may be configured to a vehicle chassis, frame, or surface.

The brackets **800**, **850** may be attached by mechanically mating and/or interlocking portions. In some instances, the brackets may be rotated relative to one another in order to engage. Once the brackets are engaged with one another, they may be substantially fixed relative to one another in a lateral and/or vertical direction. In some embodiments, once the brackets are engaged, they may not be movable relative to one another without rotating at least one of the brackets relative to another around an axis of rotation. In some embodiments, once the brackets are engaged, they may not be separable from one another via a purely translational motion.

In some embodiments, the fuel system bracket **800** may have an overhanging lip or extension **822**. The top surface **862** of the chassis bracket **850** may contact the underside of the overhanging lip or extension of the fuel system bracket. A portion of the chassis bracket may be inserted into a portion of the fuel system bracket. For example, some side walls of the fuel system bracket may surround or cover a portion **865** of the chassis bracket.

The fuel system bracket **800** may include one or more holes **820**. The one or more holes may be configured to accept one or more complementary protrusions **870** from the chassis bracket. The one or more protrusions may hook into the holes of the fuel system bracket and prevent the fuel system bracket **800** from moving laterally and/or vertically with respect to the chassis bracket **850**. In alternative embodiments, the fuel system bracket may have one or more protrusions that may fit and/or hook into one or more holes or indentation of a chassis bracket. The protrusion may optionally pass completely through the hole. The protrusion may or may not extend beyond the hole.

In some instances, a bottom surface **878** of the chassis bracket may be configured to contact with and/or engage with an interior surface **845** of the fuel system bracket. The bottom surface and the interior surface may be parallel or substantially parallel to one another when engaged. The bottom surface and/or interior surface may be slanted relative to the chassis bracket back surface **852**. In some embodiments, the bottom surface and/or the interior surface may be at a non-orthogonal angle relative to the chassis bracket back surface. The bottom surface **878** and/or the interior surface **845** being in contact may assist with keeping the brackets engaged with one another and may serve as an additional point of contact. In some embodiments, the bottom surface and/or the interior surface may have through-holes. The through-holes may align when the brackets are engaged with one another. In some instances, a fastener may pass through the aligned through-holes. The fastener may just pass through the aligned through-holes and additional holes (e.g., at the top surface of the fuel system bracket).

A back surface of the fuel system bracket **812** may be coplanar or substantially coplanar with a back surface of the chassis bracket **852**. The back surface of the fuel system bracket and/or the back surface of the chassis bracket may be configured to contact and/or engage with a vehicle chassis, frame, or surface. One or more through-holes **830** of the fuel system bracket and/or the chassis bracket may aid in the fastening of the brackets to the vehicle chassis. Alternatively, the one or more through-holes of the fuel system bracket may aid in the fastening of the fuel system bracket **800** to the fuel system.

In some instances, one or more through-holes of the fuel system bracket and the chassis may align with one another. For example, an opening **840** of the fuel system bracket may

12

align with one, two or more holes **880** of the chassis bracket. Such alignment may occur in a lateral direction. In another example, one or more top openings of the fuel system bracket **820c**, **820d**, **820e** may align with one or more top holes **875** of the chassis bracket. One or more fastener (e.g., screw, pin) may pass through aligned holes. In examples, an additional top plate may be provided over the top surfaces of the brackets **824**, **862**. The plate may be attached to the brackets via one or more fasteners that may pass through the top plate and/or aligned top holes of the bracket. Alternatively, no top plate is needed and the fasteners may pass through the aligned top holes of the bracket.

The fuel system bracket **800** may have a curved surface **802** configured to engage with a vehicle fuel system. The curved system may contact or be complementary in shape to a fuel system cover and/or fuel tank.

The brackets **800**, **850** may be configured so that they can be attached to the respective vehicle parts prior to being engaged. For example, fuel system bracket **800** may be attached to a vehicle fuel system. The chassis bracket **850** may be attached to the vehicle chassis. Such attachments may occur via fasteners passing through one or more through-holes **830**, **880**, adhesives, welding, soldering, interlocking mechanisms, rivets, or any other fastening technique. The pre-fastened brackets may be brought into engagement with one another. For example, a vehicle fuel system with an attached bracket may be lifted and mounted onto a vehicle chassis via engagement of the fuel system bracket and the chassis bracket. In some instances, a portion of the fuel system bracket may be lifted up over a portion of the chassis bracket and then brought down to settle on the chassis bracket with aid of gravity. In some instances, a combination of a top mating feature (e.g., protrusion of one of the brackets being inserted into an indentation or hole of the other bracket, and rear surface **812** of the fuel system bracket resting against a surface, such as a vehicle chassis, may keep the brackets engaged even without requiring additional fasteners or attachment techniques. Once the brackets are engaged, additional fasteners or attachment techniques may be employed to keep the brackets together, and permit the fuel system to remain mounted on the vehicle, even when the vehicle is in motion.

FIG. **8A** shows a side-front perspective view of a fuel system bracket **800** engaged with a chassis bracket **850**. The chassis bracket may be partially inserted into a portion of the fuel system bracket. Part of the chassis bracket may remain exposed. A backside **852** of the chassis bracket may be substantially coplanar with bottom back surface of the fuel system bracket **812**. A top surface **862** of the chassis bracket may be provided under an upper surface **824** of the fuel system bracket. A lip **822** of the fuel system bracket may overly a portion of the top surface of the chassis bracket. The fuel system bracket may have one or more holes **820**. Protrusions **870** of the chassis bracket may be inserted into one or more of the holes.

FIG. **8B** shows a side view of a fuel system bracket **800** engaged with a chassis bracket **850**. In some embodiments, a backside **852** of the chassis bracket and a bottom back side **812** of the fuel system bracket may be configured to contact a vehicle chassis. An upper back side **810** of the fuel system bracket may have a shape to accommodate a front side **860** of the chassis bracket. A gap may or may not be provided between the upper back side of the fuel system bracket and the front side of the chassis bracket.

FIG. **8C** shows a side view of a fuel system bracket **800** engaged with a chassis bracket **850** along with some indicators of overlap between the fuel system bracket and the chas-

13

sis bracket. A portion of the chassis bracket **865** may be inserted into a portion of the fuel system bracket. Some portions of the side walls of the fuel system bracket may overlap some portions of side walls **865** of the chassis bracket. A portion of the top surface of the chassis bracket may pass beneath an upper surface of the fuel system bracket, and protrusions may be provided at the end of the top surface of the chassis bracket. The protrusions **870** may pass through one or more holes of the fuel system bracket. A lower surface **878** of the chassis bracket may be inserted into an interior portion of the fuel system bracket.

FIG. 8D shows a front view of the fuel system bracket **800** engaged with the chassis bracket **850**. One or more through-hole **800** of the chassis bracket may be viewable and/or accessible via an opening **840** of the fuel system bracket. Optionally, a fastener or other object may pass through the opening and the through-holes.

FIG. 8E shows a rear view of the fuel system bracket **800** engaged with the chassis bracket **850**. An upper surface **824** of the fuel system bracket may overlie the upper surface of the chassis bracket. This may assist with permitting the fuel system bracket to hook on over the chassis bracket. In a drop and go bracket arrangement, the fuel system bracket may be dropped over the chassis bracket to be initially engaged. The upper rear walls **810** of the fuel system bracket may lie adjacent to the sides of the chassis bracket. The fuel system bracket may be wider than the chassis bracket, thereby permitting a portion of the chassis bracket to be inserted into the fuel system bracket. A lower surface **878** of the chassis bracket may be inserted into a portion of the fuel system bracket.

FIG. 8F shows a top view of a fuel system bracket **800** engaged with the chassis bracket **850**. The fuel system bracket may have one or more holes **820a**, **820b**, **820c**, **820d**, **820e** in its top surface. Optionally, protruding surfaces **870** from the chassis bracket may pass at least partially into the through-holes **820a**, **820b**. In some instances, the chassis bracket may have one or more underlying holes that may align with through-holes of the fuel system bracket **820c**, **820d**, **820e**.

FIG. 8G shows a side view of a separated fuel system bracket **800** and a chassis bracket **850**.

FIG. 8H shows a rear perspective view of a separate fuel system bracket **800** and chassis bracket **850**. The chassis bracket may include protrusions **870** configured to hook into holes **820a**, **820b** of the fuel system bracket. The chassis bracket may include a lower surface **878** configured to rest against an interior surface **845** of the fuel system bracket. The combination of the top interlock (between the holes and the protrusions) and the lower support (between the lower surface and interior surface) may be sufficient to keep the brackets engaged. The weight of the fuel system bracket and/or the attached vehicle fuel system may keep the fuel system bracket engaged with the chassis bracket.

In some embodiments various configurations of bracket portions may be used in order to permit a drop and go mounting of a fuel system on a vehicle. The bracket portions may be configured to mate or interlock mechanically at one point, two points, three points or more points. Such mating may occur via insertion of pins into cutouts/grooves, protrusions into indentations or holes, flanges into grooves, hook portions, or any meeting of complementary shapes or features. In some instances, at least one of the mating points may be at or near a top surface of the bracket portions. In some embodiments, the bracket portions may be engaged by a bracket portion being attached to a fuel system being dropped downward to a bracket portion being mounted on a vehicle chassis. A fuel system bracket may be dropped downward onto a

14

chassis bracket. A rotational motion may also be required to cause the bracket portions to engage. For example, the fuel system bracket may come toward the chassis bracket at an angle, and then be turned slightly to settle into engagement.

Once mechanically engaged, the bracket portions may not translate relative to one another without rotating with respect to one another, even if no fasteners are engaged at that point. The shape of the bracket interlocks and/or the gravity of the fuel system may be sufficient to keep the brackets together. Additional fasteners or components may be added to assist with stability and longevity of the connection. In some embodiments, once the bracket portions are engaged, fewer than 10, 9, 8, 7, 6, 5, 4, 3, or 2 fasteners may be employed to affix the bracket portions relative to one another. Welding or soldering steps may not be required.

FIG. 5 is a photograph of mounting of a fuel tank or system **510** using a plurality of drop and go brackets and one or more lift assist devices **540**. Each drop and go bracket may comprise a tank or system bracket **521** and a chassis bracket **522**. The chassis bracket **522** may be attached to a frame rail **501** (e.g., frame rail of a truck). The system bracket **521** may be attached to the fuel tank or system **510**. The tank bracket **521** may be dropped into place in the chassis bracket **522**, and pins, protrusions, holding plates and or other connecting means may mate/connect together to lock the bracket in place. The brackets may then optionally be attached together with a single plate on top (not shown), as described elsewhere herein.

The fuel tank or system **510** may be any fuel system described herein, including but not limited to a fuel tank housed in a cover, a fuel tank partially housed in a cover or a fuel tank not housed in a cover. For example, the bracket **521** may be attached to the fuel tank **510** (e.g., Diesel fuel tank, as shown in FIG. 5, or an LNG tank), wherein the fuel tank may or may not be housed in a cover. In another example, a CNG or LNG tank may be housed in a cover.

The fuel tank or system **510** may be attached to the bracket **521** via one or more mating connectors or attachment members, such as mating, connecting or attachment members described elsewhere herein. For example, the bracket **521** may be secured to the fuel system via one or more bolts, with corresponding apertures or connecting members provided on the bracket **521** and the system **510**. In cases where the fuel system comprises a cover, the cover may be bolted to the system bracket **521**. In some cases where the fuel system does not comprise a cover, the fuel tank may be bolted to the tank or system bracket **521**. The members may further include one or more straps **550**, which may be used to attach the bracket **521** to the fuel tank **510**. For example, the strap **550** may be non-rotatably secured to the tank **510**, with the bracket **521** securely attached to or integrally formed with the strap **550**. In some cases, the fuel tank **510** may not be attached using the strap **550** but may use other means to connect the tank to structural mounting points, such as, for example, in a case where the tank is supported at each end of the tank, with the weight supported on the tank boss or neck. The drop and go mounting may be used for mounting one or more neck mounts. For example, the fuel tank or system **510** may be neck mounted to the vehicle using one or more drop and go brackets. One or more drop and go brackets may be used to mount the fuel tank or system **510** in one or more locations, including but not limited to the tank or system body, one or more ends, one or more necks and/or any other structural mounting points or members. The drop and go mounting may be facilitated by the lift assist devices **540**. The fuel tank **510** may be lifted and positioned by the lift assist devices **540** with gun turret-like construction required to lift the tank assembly and

15

drop it onto the chassis bracket **522**. The drop and go mounting may permit fuel systems to be mounted onto a vehicle without removing the vehicle from an assembly line.

Regardless of fuel system used, the drop and go bracket may be accessed from one or more directions indicated in FIG. **5**. Access may be provided prior to, during, and after dropping the fuel system **510** with bracket **521** onto the bracket **522**. For example, the drop and go bracket may be accessed from a top direction **570a** when the brackets **521** and **522** have engaged in order to fasten connectors and/or to fasten the top plate. The fasteners may then be installed from the top direction **570a** outside the vehicle. In another example, access may be provided from the top direction **570a** and/or a side direction **570b** during engagement of the brackets **521**, **522** to assure proper alignment during engagement. In some embodiments, access may be provided from the bottom direction **570c**. In some embodiments, an impact wrench may be used to bolt fasteners on the drop and go bracket, the bracket holding the fuel tank or system (e.g., after engagement of brackets **521**, **522**, wherein the fuel tank or system is held by the bracket to the frame **501**). The drop and go bracket may enable access from the top direction **570a**, the side direction **570b** and/or the bottom direction **570c**. For example, when the fuel system **510** is a CNG or LNG fuel system housed in a cover, the drop and go bracket may enable top access **570a** in order to fasten connectors and/or perform mounting tasks while the fuel system is held by the bracket. In another example, a fuel tank, such as a Diesel fuel tank, may be held by the drop and go bracket, and one or more access directions **570a** or **570b** may be provided.

One or more belly straps **560** shown in FIG. **5** may or may not be used to provide additional safety, independently of the drop and go brackets and lift assist devices.

The invention may offer significant advantages with respect to existing options for mounting fuel systems to vehicles, such as, for example, the installation of a fuel tank to a vehicle at original equipment manufacturer (OEM) factories. For example, the drop and go bracket disclosed herein may be used by vehicle OEMs to install CNG or LNG tanks on the production line, thereby reducing production time so that the tanks can be installed on the line instead of in a retrofit shop after final vehicle assembly. Currently, side-mounted compressed gas tanks are rigidly mounted to the chassis in a complicated and lengthy procedure that requires the vehicle be taken off of the assembly line to install the tanks. This procedure can take hours. The drop and go bracket system provided herein can drastically reduce the installation time at OEM factories (e.g., to a few minutes). Systems and methods provided herein may also be used for quick mounting of other frame mounted vehicle equipment, such as hydraulic tanks, battery boxes, tool boxes, etc.

The systems and methods herein may also be advantageously applied to enable reliable, rapid and safe mounting of vehicle fuel systems during replacement and/or retrofitting of existing vehicle fleets.

While preferable embodiments of the present invention have been shown and described herein, it will be obvious to those skilled in the art that such embodiments are provided by way of example only. Numerous variations, changes, and substitutions will now occur to those skilled in the art without departing from the invention. It should be understood that various alternatives to the embodiments of the invention described herein may be employed in practicing the invention. It is intended that the following claims define the scope of the invention and that methods and structures within the scope of these claims and their equivalents be covered thereby.

16

What is claimed is:

1. A drop and go bracket comprising:

a first bracket portion configured to be attached to a vehicle chassis, wherein the first bracket portion includes a groove and a pin at a separate location from the groove; and

a second bracket portion configured to be attached to a vehicle fuel system, wherein the first bracket portion and the second bracket portion are configured to be engaged and connected to one another in a manner that (i) mounts the vehicle fuel system to the vehicle chassis and (ii) prevents substantial translation without rotation between the first bracket portion and the second bracket portion in a lateral direction and in a vertical direction without the aid of additional fasteners, wherein the second bracket portion includes a cut-out configured to engage with the pin of the first bracket portion when part of the second bracket portion slides into the groove of the first bracket.

2. The bracket of claim **1** wherein the portion of the second bracket portion that slides into the groove is a pin.

3. The bracket of claim **1** wherein the first bracket portion and the second bracket portion have flat tops configured to accept a plate flush against the flat tops.

4. The bracket of claim **1** wherein the first bracket portion includes one or more holes or indentations at a top surface of the first bracket.

5. The bracket of claim **4** wherein the second bracket portion includes one or more protrusions configured to be inserted into the one or more holes or indentations.

6. A vehicle fuel mounting system comprising:

a first bracket portion attached to a vehicle chassis, wherein the first bracket portion includes (1) a groove, indentation, or hole and (2) a pin at a separate location from the groove, indentation, or hole; and

a second bracket portion attached to a vehicle fuel system, wherein the first bracket portion and the second bracket portion are configured to be engaged and interlock in order to mount the vehicle fuel system to the vehicle chassis without the aid of additional fasteners, wherein the second bracket portion includes a cut-out configured to engage with the pin of the first bracket portion when part of the second bracket portion slides into the groove, indentation, or hole of the first bracket portion.

7. The system of claim **6** wherein the first bracket portion includes the groove and the part of the second bracket portion that engages or interlocks the groove is a pin.

8. The system of claim **6** wherein the first bracket portion and second bracket portion are configured to be movable relative to one another after being engaged only if the first bracket portion rotates relative to the second bracket portion.

9. The system of claim **6** wherein the vehicle fuel system includes one or more tanks containing compressed natural gas or liquefied natural gas.

10. A method for mounting a fuel system to a vehicle comprising:

attaching a first bracket portion to a vehicle chassis;
attaching a second bracket portion to a vehicle fuel system;
attaching the second bracket portion attached to the vehicle fuel system to the first bracket portion attached to the vehicle by one or more of the following: (i) sliding a part of the first bracket portion into a cutout, indentation, or hole of the second bracket portion, or (ii) sliding a part of the second bracket portion into a cutout, indentation, or hole of the first bracket portion; and

attaching a plate to both a top surface of the first bracket portion and a top surface of the second bracket portion.

11. The method of claim 10 wherein the part of the first bracket portion is a pin, or the part of the second bracket portion is the pin.

12. The method of claim 11 wherein attaching the second bracket portion to the first bracket portion includes sliding the pin of the first bracket into the cutout of the second bracket portion and sliding the pin of the second bracket portion into the cutout of the first bracket portion. 5

13. The method of claim 10 wherein the part of the first bracket portion is a protrusion, or the part of the second bracket portion is a protrusion. 10

14. The method of claim 10 wherein the second bracket portion is attached to the first bracket portion while the vehicle is on an assembly line.

15. A drop and go bracket comprising: 15

a first bracket portion configured to be attached to a vehicle chassis, wherein the first bracket portion comprises one or more holes or indentations at a top surface of the first bracket; and

a second bracket portion configured to be attached to a vehicle fuel system, wherein the first bracket portion and the second bracket are configured to be engaged and connected to one another in a manner that (i) mounts the vehicle fuel system to the vehicle chassis and (ii) prevents substantial translation without rotation between the first bracket portion and the second bracket portion in a lateral direction and in a vertical direction without the aid of additional fasteners. 20 25

16. The drop and go bracket of claim 15, wherein the second bracket portion includes one or more protrusions configured to be inserted into the one or more holes or indentations. 30
